ALL TRANSISTOR TRANSOCEANIC PORTABLE RECEIVER

CHASSIS 9HT41Z2

To the Serviceman

GENERAL

The transistor portable chassis is a conventional super-heterodyne receiver using an individual mixer and oscillator to produce the 455 Kc intermediate frequency. The intermediate frequency amplifiers are conventional. It was necessary to neutralize the I.F. amplifier stages as in circuits using a triode tube. The diode 103-31 is used as a detector and AVC voltage source. This diode is part of I.F. Transformer T7. This is then followed by a first audio amplifier and a driver stage for the class B push-pull output. The 121-47 output transistors are a matched pair and will be coded with paint dots, red, white, yellow and green. Should one transistor fail it must be replaced with another 121-47 transistor with corresponding color. Do not use 121-47 transistors in pairs unless their color codes are identical.

The iron core slugs of the RF, mixer and oscillator coils have hexholes through their centers. This will enable the technician to tune the top slug then drop the alignment wrench No. 68-32 down through the slug to adjust the slug in the lower coil.

Power Supply — Eight Zenith Z2NL 1½ volt or Standard Flashlight Batteries total 12 volts D.C. Approximate battery life 300 hours. One Zenith Z2NL 1½ volt or Standard Flashlight Battery for the dial light.

Frequency Ranges:	9.4 to 10 Mc
150 to 400 Kc	11.4 to 12.2 Mc
540 to 1600 Kc	14.7 to 15.7 Mc
2 to 4 Mc	17.1 to 18.5 Mc
4 to 9 Mc	20.7 to 22.4 Mc

Intermediate Frequency: 455 Kc

Power Output Undistorted: 500 Milliwatts

Speaker: 4 inch P.M.

Alnico V, Voice Coil Impedance — 3.2 ohms @ 1000 cycles

Accessory Earphone 39-24 Impedance 15 ohms @ 1000 cycles

Current drain under no signal conditions with volume control at minimum is approximately 14.5 milliamperes.

RESISTANCE MEASUREMENTS

When making resistance measurements in the circuit, it is most important to remove the transistors in the circuit under test otherwise readings obtained will be incorrect. This is the direct result of a transistor acting as a diode.

When making measurements across an electrolytic capacitor, be certain the ohm meter leads are correctly polarized; also be certain the battery voltage of the meter does not exceed the working voltage of the capacitor. Otherwise damage to the capacitor may result.

VOLTAGE READINGS

It is suggested that a VTVM with an excellent low range scale be used to measure all circuit voltages. All voltages indicated on the accompanying diagrams have been measured under no signal conditions and a carbon battery supply voltage of 12.0 volts. Under these no signal conditions, a check can be made of the batteries. With carbon batteries, the total voltage should be 12.0 volts.

COMPONENT REPLACEMENT

When soldering components at the base of the transistor socket, it is suggested that the transistor be removed to avoid any possibility of excessive heat being transferred through the socket to the transistor. When soldering the low voltage electrolytics and germanium diodes, it is suggested that the wire be held with a pair of long nose pliers while soldering. The long nose pliers will act as a heat sink.

TRANSISTORS

There are several good transistor testers; one is The Hicock Model 870, another would be the Simpson 650 which must be used in conjunction with either a Simpson 260 or 270 V.O.M. Should this test equipment not be available a good reliable check is to substitute a new transistor and then check performance. There is a possibility that if transistors are replaced in the IF or RF circuit, these circuits may need re-alignment as the result of slight differences in transistor characteristics.

SIGNAL TRACING

Past practices used in radio repair commonly known as "screw driver testing" in which the B+ at the plate of the tube is shorted to ground to check for "clicks" in the speaker, is definitely not recommended. This practice would be comparable to shorting the collector of a transistor

to ground which could damage the transistor. Standard point to point signal checking with the proper RF, IF and audio signals, should only be used.

REPAIR EQUIPMENT

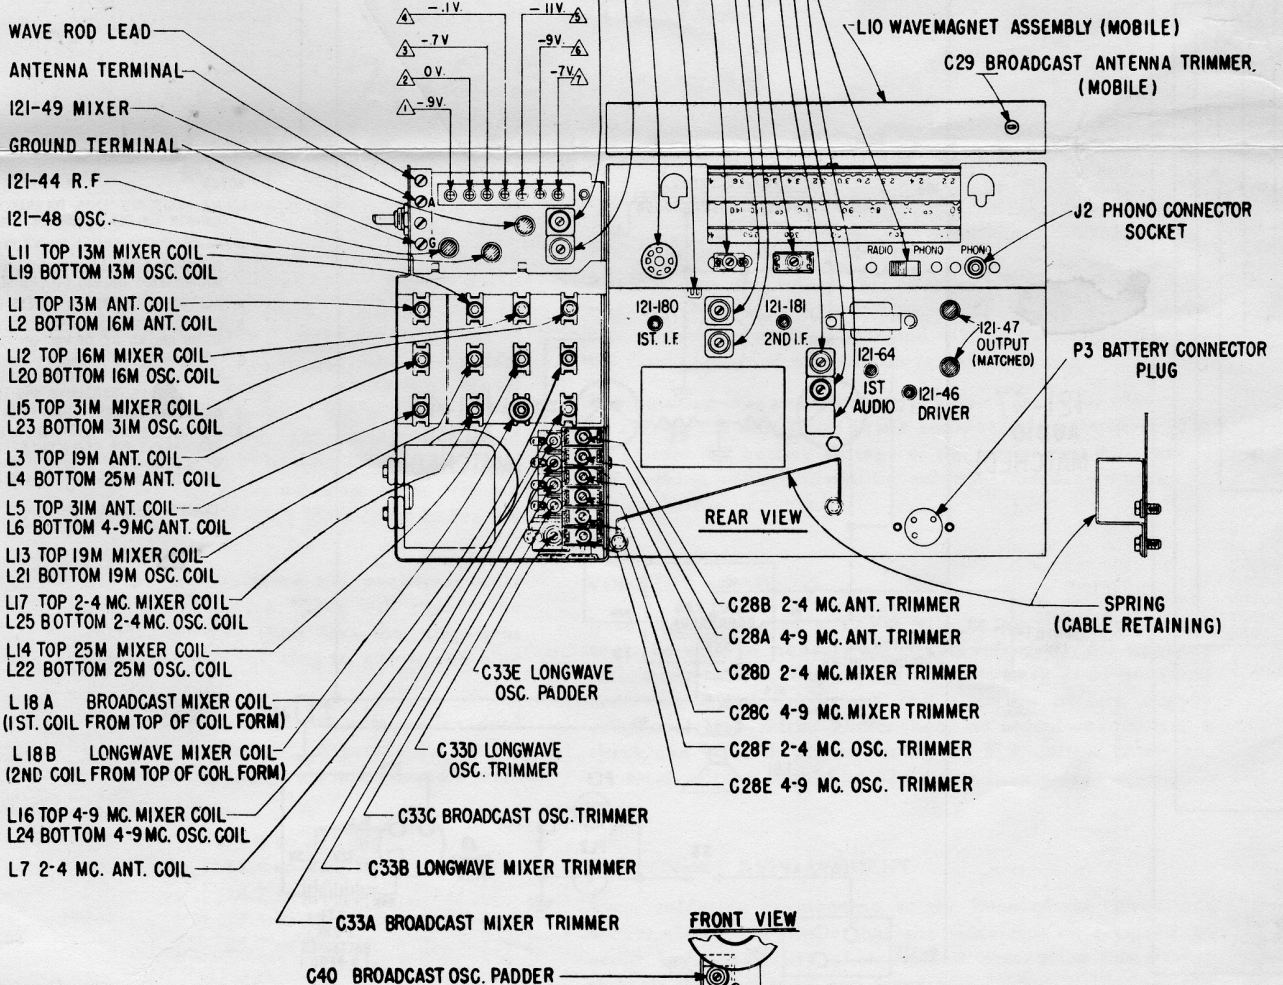

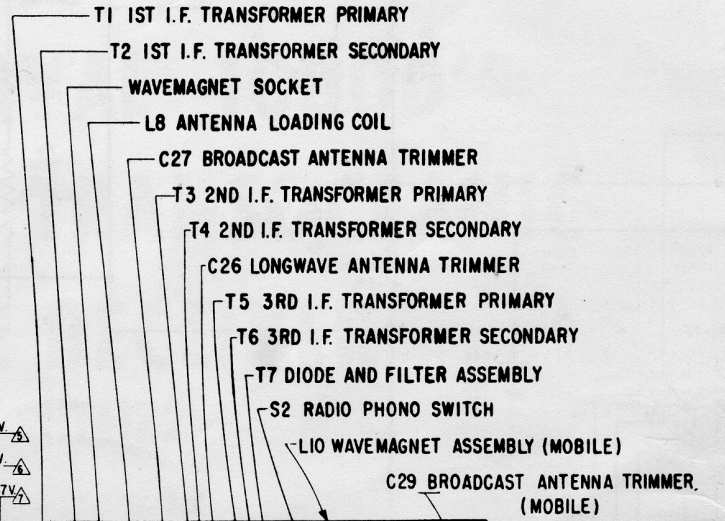

The following list of equipment is what we recommend and use for repair of transistor chassis:

1. An RF signal generator supplying frequencies from 150 Kc to 23 Mc.
2. An audio generator or an audio signal source to be used for signal tracing after the diode detector.
3. A VTVM with a good low range voltage scale and a reliable resistance scale.
4. M209B Dazor floating lamp & magnifier or equivalent.
5. A set of optometrist tools - pliers, cutters, picks, etc.
6. A soldering iron with a very fine tip, not to exceed 35 watts.
